

Stage-by-Stage Impact of Blind Hiring

0 Summary

1 Treatment Effect of Blinding on Hiring Outcomes (Stage-by-Stage Analysis)

1.1 Blinding Disrupts Pre-Existing System of Demographic Premiums and Penalties

- **Finding (i):** Blinding demographic information during candidate evaluation *disrupts* a pre-existing system of *demographic premiums and penalties*.
- **Finding (ii):** Blind hiring removes the *baseline premium and penalty* that different demographic groups were experiencing at different phases of the hiring pipeline.
 - **Winners: Hispanic Female in Resume-Screening (Phase 1) and White Male in Technical-Evaluation (Phase 2).** Blinding removes the baseline *penalty* these groups received under non-blind evaluations. Their evaluation scores rise by **+8.7%** and **+8.6%** of a SD respectively.
 - **Losers: Hispanic Male in Phase 1 and Hispanic Female in Phase 2.** Blinding removes the baseline *premium* these groups received under non-blind evaluations. Their evaluation scores fall by **-11.5%** and **-6.9%** of a SD respectively.
- **Caveat:** Hiring is often an *ordinal ranking* problem — one candidate’s gain corresponds to another’s lost opportunity — so the absence of statistical significance on a given row does not mean the corresponding group is unaffected by blinding.

Effects of Blinding on Overall Evaluation Score	Panel A: Resume-Screening Phase	Panel B: Technical-Evaluation Phase
	HR	Engineer
White Male	0.037 (0.058)	0.086*** (0.028)

1.1.1 Heterogeneity: Rejecting Traditional In-Group Favoritism

- **Findings:** Our experiment demonstrates that engineers in the I.T. industry, when hiring for early-career software engineer roles, operate on a preference for the *out-group* (i.e., a preference for *under-represented groups*).
 - When demographic information is blinded, the scores of *concordant* (race/gender) applicants evaluated by Engineers rise by **+6.9%** of a SD ($p < 0.05$), while the scores of *discordant* applicants fall by **-0.9%** of a SD ($p < 0.05$).
 - White Males make up the majority of the evaluator pool for engineers, and their behavior drives the aggregate results.
- **Takeaway:** The majority gatekeepers were *actively penalizing* candidates who looked like themselves and assigning a *premium to evaluation scores of minority candidates* when such demographic information is visible. Enforcing blind hiring stops the majority group, White Males, from systematically boosting the minority candidates. This explains why, in our experiment, White Male applicants are the primary beneficiaries of blind hiring: they are “rescued” from the baseline penalty imposed by their own demographic engineer peers.

1.1.2 Heterogeneity: Where the Demographic Premium Applies (Effects by Candidate Quality)

- **Findings:** The blinding effect on evaluation scores *diverges across visible candidate quality* — GPA and Coding Ability (the success rate of the submitted code) — within the same demographic group. The implicit out-group premium documented in §1.1.1 is concentrated at the *top* of the ability distribution.
 - **Hispanic Male.** Blinding lowers Hispanic Male evaluation scores, with the drop concentrated at the *Top* tier in both phases. Elite Hispanic Males appear to enjoy a contextualization premium under nonblind that blinding removes.
 - **Hispanic Female.** The same premium-at-top pattern appears in Phase 2 (Eng / Coding Ability). The Phase 1 (HR / GPA) pattern *reverses* — HF candidates face the largest demographic-driven discount at the Top tier under nonblind, consistent with §1.1’s finding that HF *win* in Phase 1 but *lose* in Phase 2.
 - **Non-Hispanic Female (White / Asian).** Premium-at-top pattern again appears in Phase 2 along the Coding Ability dimension; the GPA dimension shows the same direction with weaker magnitudes.
 - **White Male (mirror).** Blinding raises White Male scores roughly *uniformly* across all three tiers in both phases. The in-group discount under nonblind is a *flat demographic shift*, not conditional on observable ability.

Heterogeneous Effect of Blinding on Evaluation Score by Demographic Group & Candidate Quality (Low, Mid, High Ability)

1.2 Blinding Reshuffles Demographics of Hired (Composition Effect)

Specification. The §1.1 evaluation-score result is a per-resume *rating* effect; this subsection asks how the rating effect translates into a *selection* effect at the cohort level. For each $k = 1, \dots, 18$ and each role, we regress the binary selection indicator (`hr_passk` for HR, `eng_topk` for Engineer) on the assigned race-gender, with `Blind` as the reference category. The reported coefficient is the *blinding effect* (sign-flipped post-fit so positive $\Rightarrow$ blinding raises the probability that this demographic is selected at top- k).

Effect of Blind Hiring on Selection Probability by Demographic Group

Blinding effect = $-(\text{effect of revealing identity vs blind})$. Positive = more likely selected under blinding.

Evaluator Role ● HR Stage ● Engineer Stage

Significance: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. Base group: Blind resumes.

2 Effect of Blinding on Evaluation Behavior

2.1 On Evaluation Effort: Time Spent and Material Engagement

Placeholder. Forthcoming: regressions of evaluator time-spent and material-engagement (proportion of code / resume opens) on **treat**.

2.2 On Signal Substitution — Re-weighting of Visible Resume Cues

Specification. Once forced to reconstruct judgment, what *visible* resume signals does the evaluator lean on more (or less) under blinding? We pool the candidate-evaluator panel and regress the evaluator’s overall rating on each visible signal $\times$ Blind interaction:

$$\text{sc_overall_z}_{ij} \sim \sum_{s \in \mathcal{S}_{role}} \beta_s \text{Signal}_s^i \times \mathbb{1}[\text{Blind}]_j \mid \text{resume_index}_i + \text{responseid}_j + \text{r_do}_{ij}.$$

With **resume_index** FE absorbing every resume-level main effect (each signal is constant within a resume) and **responseid** FE absorbing every respondent-level main effect (including **treat**), the surviving coefficients $\hat{\beta}_s$ are exactly the *change* in evaluator weight on signal s when we move from non-blind to blind review. Positive $\hat{\beta}_s \Rightarrow$ blinding causes evaluators to weigh signal s *more heavily* than they did under nonblind. Whether each shift is rational depends on the signal’s *validity* for true coding ability — which §6 evaluates.

Visibility-tailored signal sets. HR sees the resume only; Engineers see the resume plus the candidate’s actual code submission (so they observe **test_case** and the language used). Latent lab measurements (**readability**, **time/space_efficiency**) are unobserved by both sides and are the *outcome* in §4, not RHS signals here.

Spec (compact): $\text{sc_overall_z} \sim (\text{Signal}) \times \text{Blind} \mid \text{resume_index} + \text{responseid} + \text{r_do}$; two-way clustered SEs on (**responseid**, **resume_id**). Reported coefficients are **Signal** $\times$ **Blind** interactions (*change* in evaluator weight on the signal under blinding); main effects are absorbed by the FEs.

Table 1: Signal Substitution — coefficient on each visible-signal $\times$ Blind interaction (the change in evaluator weight on the signal under blinding). Outcome: `sc_overall_z`. Resume content (`resume_index`), display position (`r_do`), and respondent (`responseid`) FEs absorb all main effects. **Omitted (no within-sample identification or endogenous):** `python` and `java` (listed by every candidate); `q1_cplusplus` / `q2_cplusplus` (no candidate submitted in C++); `q1_python` / `q1_java` / `q2_python` / `q2_java` (collinear with the listed-language binaries); `code_opt_out` (endogenous: students self-select into opting out based on their own code quality). Two-way clustered SEs on (respondent, resume) in parentheses.

Coefficient on each visible-signal x Blind interaction (the change in evaluator weight on the signal under blinding)

Positive: blinding makes the evaluator weigh this signal MORE than they did under non-blind. Q1/Q2 language indicators: C++ is the omitted reference category. Bars: 95% CI for Significance: * p<0.10, ** p<0.05, *** p<0.01.

2.3 On Internal Rubric — Coding / Fit / Stay Aggregation

Specification. Decompose the evaluator’s overall rating into the three sub-dimension ratings and ask whether their relative weights shift under blinding:

$$sc_overall_z_{ij} \sim (sc_coding_z + sc_fit_z + sc_stay_z) \times \mathbb{1}[\text{Blind}]_j \mid responseid_j + resume_index_i + r_do_{ij}.$$

With **responseid** FE absorbing all between-respondent terms (including **treat**), **resume_index** FE absorbing all resume-level constants, and **r_do** FE absorbing display-order, the surviving coefficients are: (a) three *level* coefs (the nonblind weight each sub-dimension gets in the overall rating), and (b) three $\times$ **Blind** interactions (the change in each weight under blinding). Two-way clustered SEs on (**responseid**, **resume_id**). The hypothesis: *Coding* weight rises and *Fit* weight falls under blinding.

Table 2: Internal Rubric Shift — decomposition of **sc_overall_z** into Coding / Fit / Stay sub-dimension ratings and their interactions with Blind. Resume content (**resume_index**), display position (**r_do**), and respondent (**responseid**) FEs absorb all main effects (incl. **treat**). Level coefs = nonblind weight on each sub-dimension; $\times$ **Blind** coefs = how blinding shifts those weights. Two-way clustered SEs on (respondent, resume) in parentheses.

3 Signal Validity: Are Visible Signals Predictive of True Coding Ability?

Why this matters. §5 shows that under blinding, evaluators reweight their attention onto visible resume signals — but a positive weight-shift only counts as **rational** signal substitution'' if those signals **\emph{actually predict}** true productivity. If the signals blinding pushes evaluators toward have zero validity, the §5 effect is just **\emph{credentialism}** (the flight to credentials'' hypothesis). This section provides the validity benchmark.

Why univariate (and not multivariate). A multivariate spec — regressing `true_coding_z` on all 15–17 visible signals jointly — is over-determined here: `true_coding_z` is constant within `resume_index`, so the panel of 5,238 candidate-evaluator observations collapses to just 18 effective cross-resume observations. With 15 signals (HR-visible) the multivariate regression has only ~ 2 residual degrees of freedom; with 17 signals (Eng-visible, including `test_case_z`) it is exact-fit ($R^2=1$) because `overall_score` mechanically equals `test_case` + `readability` + `time_efficiency` + `space_efficiency`. We therefore report *univariate marginal validity* for each signal — one OLS regression per signal at the resume level (18 observations), HC1 robust SE.

Specification (univariate, per signal).

$$\text{true_coding_z}_i \sim \alpha + \gamma_s \text{Signal}_s^i + \varepsilon_i, \quad i = 1, \dots, 18, \quad \text{vcov} = \text{HC1}.$$

The estimand $\hat{\gamma}_s$ is the cross-resume marginal slope of objective ability on signal s . It is the right object to compare against §5's signal $\times$ Blind coefficient: §5 measures how much blinding shifts evaluators' weight on a signal; §6 measures whether that signal correlates with truth. The combination tells us whether each blinding-induced shift is rational or pure credentialism.

Table 3: Signal Validity — univariate cross-resume slope of `true_coding_z` on each visible signal. One OLS regression per signal at the resume level ($N=18$). Estimate (HC1 robust SE) with significance stars; per-signal R^2 . **Why univariate, not multivariate:** the multivariate spec is over-determined — 15–17 signals against 18 effective cross-resume observations leaves ≤ 2 residual DOF; the Eng spec exact-fits because `overall_score` = `test_case` + `readability` + `time_efficiency` + `space_efficiency`. Stars: * $p<0.10$, ** $p<0.05$, *** $p<0.01$.

Signal weight shift under blinding (§5, multivariate) vs. signal validity for true coding ability (§6, univariate)

Top-right quadrant: rational reweighting (blinding shifts evaluators toward genuinely predictive signals). Top-left: missed opportunity. Bottom-right: flight to credentials (blinding shifts toward signals with no validity). B

3.0.1 Consolidated Story (§5.1 + §5.2 + §6 → §4 null)

Reading the three pieces together:

1. **Step 1 (§5.1) — null.** The hypothesis was that blinding, by stripping demographic loading from the *Fit* subscale, would force evaluators to up-weight *Coding*

and down-weight *Fit* in their overall rating. The data reject this: *none* of the six **Coding/Fit/Stay** $\times$ **Blind** interaction coefficients in §5.1 are statistically distinguishable from zero (point estimates all in $[-0.06, +0.04]$ with SEs ~ 0.05 , for both HR and Eng). The internal scoring rubric is *stable* across treatment arms.

2. **Step 2 (§5.2) — where the action is.** Because Step 1 is null, the entire blinding-induced reweighting must operate at the external-proxy level. §5.2 shows large and significant shifts in the visible signals evaluators rely on under blinding (the engineer side’s biggest positive shifts: New Startup, Teaching Position, JavaScript-listed; biggest negative: GPA, C#-listed).
3. **Validity check (§6).** The univariate regressions on the same 18-resume sample show which of those signals *actually predict* true coding ability. The §5.2 vs §6 scatter is the headline figure: signals in the bottom-right quadrant (positive §5.2 weight shift, near-zero §6 validity) are the “flight to credentials” — blinding redirects the evaluator’s attention to low-validity heuristics, despite leaving the Coding/Fit/Stay weighting intact.

Why §4’s productivity-of-hired effect is null. The reconstruction is entirely external (Step 2), not internal (Step 1): the evaluator’s overall rating is still built from Coding / Fit / Stay in the same proportions as before, but the Coding judgment that goes into that mixture is now itself drawn from a different — and largely lower-validity — bundle of resume cues. Blinding does not break the rubric, but it does redirect the rubric’s inputs through credentialist heuristics. Net efficiency: zero gain.

4 Individual Response to Institutional Policy (Institutional Crowding Out or Compensatory Bias)

Takeaway / Summary.

- **The Puzzle of Individual Ideology:** The two-way relationship between an evaluator’s personal DEI priority and their evaluation scores is surprisingly *muted and statistically noisy*. At first glance, personal ideology appears to have little impact on how blind hiring reshuffles outcomes.
 - **Compensatory Bias** (Firms with NO Diversity Mandate, see [red lines](#)): When a firm lacks an explicit objective policy targeting URMs, highly pro-DEI HR professionals engage in *compensatory bias* — filling the perceived institutional void by informally inflating minority candidates’ scores in the baseline.
 - **Institutional Crowding-Out** (Firms WITH a Diversity Mandate, see [blue lines](#)): Conversely, when the firm explicitly mandates URM targeting, this formal policy *crowds out* the evaluator’s informal efforts; pro-DEI HR professionals *mute* their premium to under-represented minorities’ scores.
- (Note the *divergence between HR and Engineer results*, particularly in the triple-interaction columns.)

Note on Key Index Creation.

- *Individual DEI Index (Z)*: Evaluator’s personal DEI orientation, condensed into a single z-scored score. (Low = Anti-DEI, High = Pro-DEI)
 - Mathematical expression: $\text{Index} = z\left(\frac{1}{5} \sum_{j=1}^5 z(x_j)\right)$, z-scored within (**role**, **treat**) cells.
 - **pro_dei_race** — stated agreement that race DEI is important in hiring (Likert).
 - **pro_dei_gender** — stated agreement that gender DEI is important in hiring (Likert).
 - **pro_diverse** — stated importance of working at a company with a diverse workforce (Likert).
 - **pro_hiring_dei** — stated belief that DEI initiatives help firms hire better candidates (Likert).
 - **div_priority** — revealed-priority rank of “Diversity and Representation” in the seven-goals question.
- *Firm Targets Fem/His (0/1)*: Indicator for firm policy — whether the evaluator’s firm formally targets Female or Hispanic candidates in hiring.
 - Mathematical expression: $\text{Idx} = \mathbb{I}\{\text{firm_targets_female} = 1 \vee \text{firm_targets_hispanic} = 1\}$.
 - **firm_targets_female** — 1 if option 6 (“Female”) was selected on **s5_policy_diversity** (multi-select).
 - **firm_targets_hispanic** — 1 if option 3 (“Hispanic or Latino”) was selected on the same multi-select.
- *Firm DEI Attn Index (Z)*: Respondent’s perception of how much attention their firm currently pays to race and gender DEI in hiring, condensed into a single z-scored score.
 - Mathematical expression: $\text{Index} = z\left(\frac{1}{2}(z(\text{race_attn}) + z(\text{gender_attn}))\right)$, z-scored within (**role**, **treat**) cells.
 - **s5_view_dei_race_f** — Likert: respondent’s perception of firm’s current attention to race DEI in hiring.
 - **s5_view_dei_gender_f** — Likert: respondent’s perception of firm’s current attention to gender DEI in hiring.

* p < 0.1, ** p < 0.05, *** p < 0.01

Standard errors clustered by respondent.

Marginal-effects “scissors” plot built from the §2.3 columns 3-4 (HR & Engineer triple with Firm Targets Fem/His) under the URM-Tech dichotomy. Top row: HR evaluators (Panels A1, B1). Bottom row: Engineer evaluators (Panels A2, B2). Lines: predicted effect of blinding on each group’s overall score as a function of the rater’s Individual DEI Index (Z); shaded bands are 95% CIs (SE clustered by respondent).

5 Inter-Departmental Backlash and Compensation: Signed Directional Index

Spec. Triple-interaction model with a **signed, DEI-specific, directional** perception index per role: positive end captures the role-appropriate “misalignment in the bad direction” (HR overreach for Eng; Eng undercare for HR); negative end captures the opposite direction. Both directions are continuous, not thresholded.

Survey directional structure (used directly). The multi-select options `aligndiff{role}_1..6` record which DEI dimensions the respondent flagged, and the items themselves are directional:

- Options 1 / 4: counterpart places *higher* priority on gender / racial diversity (rebellion-relevant for Eng; over-care-relevant for HR).
- Options 2 / 5: counterpart places *lower* priority on gender / racial diversity (under-care-relevant for HR; opposite-direction signal for Eng).
- Options 3 / 6: counterpart places priority on *different* groups (no direction — ignored here).

Index construction (per role; respondent-level then merged back):

- **Eng (HR Overreach direction).** Likert: `s5_hr_influence` (1–4, “to what extent does HR push DEI in hiring”; higher = more push). Directional count: $(\text{aligndiffeng}_1 + \text{aligndiffeng}_4) - (\text{aligndiffeng}_2 + \text{aligndiffeng}_5)$ (positive = HR cares more on race/gender DEI; negative = HR cares less). Composite: `eng_dir = s5_hr_influence + 0.5 · directional_count`, then z-scored within Eng.
- **HR (Eng Undercare direction).** Likert: `-s5_engineer_care` (negated 0–4 “to what extent does Eng prioritize DEI”; higher negated = Eng cares less). Directional count: $(\text{aligndiffhr}_2 + \text{aligndiffhr}_5) - (\text{aligndiffhr}_1 + \text{aligndiffhr}_4)$ (positive = Eng cares less on race/gender DEI; negative = Eng cares more). Composite: `hr_dir = -s5_engineer_care + 0.5 · directional_count`, then z-scored within HR.
- `misalign_z = eng_dir_z` for Eng rows / `hr_dir_z` for HR rows, used as `perc_role` in the regressions. Sample inclusion: drop only respondents NA on the Likert anchor (`s5_hr_influence` for Eng / `s5_engineer_care` for HR).

Substantive interpretation. `perc_role > 0` = rebellion conditions'' for Eng /compensation conditions'' for HR; `perc_role < 0` = the opposite direction (Eng who think HR underreaches; HR who think Eng overcares). Triple-interaction slopes can therefore be read as: *how does the effect of blinding on group X change as the rater moves from “counterpart cares too little on DEI” to “counterpart cares too much on DEI”?*

6 Treatment Effect on Productivity of Hired (The Efficiency Myth)

Signal Extraction Remains Flat (S5.1.): Removing demographic information (or noise) does *not* meaningfully improve their ability to identify top ability candidates.

Quality of Hires Does Not Improve (S5.2.): Blind hiring has a *null* effect on the actual coding quality of the hired cohort.

6.1 Does Blinding Lead to More Accurate Coding Skill Evaluations?

Specification:

Hiring Evaluation Score (Z) $\sim$ True Coding Ability (Z) $\times$ 1[Blind arm] | Respondent FE + Display Position FE.

- $H_0: \beta = 0$ — the evaluator extracts *no signal* from true coding ability.
- $H_0: \beta = 1$ — the evaluator is *perfectly calibrated*: a 1 SD rise in true ability produces exactly a 1 SD rise in the rating, with no shrinkage.

	HR	Engineer
$\hat{\beta}_{\text{nonblind}}$ (slope, nonblind arm)	0.378 (0.029)	0.885 (0.013)
$\hat{\beta}_{\text{blind}}$ (slope, blind arm)	0.356 (0.023)	0.855 (0.015)
Observations	2,466	2,772
R^2	0.142	0.758
Adj. R^2	0.085	0.742
Resume (Content) FE	×	×
Display Position FE	✓	✓
Respondent FE	✓	✓
Respondent Characteristics	×	×

Cluster-robust standard errors (by respondent) shown in parentheses next to each $\hat{\beta}$. Stars on p-values: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

6.2 Does Blinding Lead to Selection of More Productive Coders?

Treatment effect on true productivity measure (coding lab evaluation) of selected candidates, standardized relative to selected candidates under no blind

Positive = blind hiring selects candidates with higher actual coding scores.
Significance: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 4: Per- k blinding TE on actual coding score (HR vs Engineer). Cells: estimate (clustered SE). Stars: $*p<0.10$, $**p<0.05$, $***p<0.01$.

k	HR Stage	Engineer Stage
1	0.005 (0.164)	-0.200 (0.163)
2	-0.054 (0.100)	-0.103 (0.110)
3	-0.010 (0.079)	-0.077 (0.082)
4	0.004 (0.066)	-0.043 (0.084)

14	0.008 (0.020)	-0.014 (0.012)
15	-0.001 (0.018)	-0.019* (0.010)
16	-0.020 (0.014)	-0.021** (0.008)
17	0.002 (0.009)	-0.002 (0.005)
18	-0.000 (0.000)	0.000 (0.000)

6.2.1 Component Decomposition (`test_case`, `readability`, `time_efficiency`, `space_efficiency`)

`overall_score` above is a composite index over four lab subscores. Decomposing the per- k TE into each component reveals which dimension of objective coding quality blinding actually shifts. **Visibility note:** engineers see `test_case` numbers directly on the resume; HR sees none of these, and neither side sees `readability`, `time_efficiency`, or `space_efficiency` (latent lab measurements).

Per-component decomposition of TE on selected candidate quality (each component standardized per k relative to nonblind)

Visibility: engineers see test_case directly; HR sees none. Readability / time / space are unobserved by both sides (latent lab measurements).
Significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 5: Per- k blinding TE on each coding component (standardized per k relative to nonblind). Cells: estimate (clustered SE on respondent). Stars: $*p<0.10$, $**p<0.05$, $***p<0.01$.

6.3 Does Blinding’s Productivity Effect Differ by Evaluator’s DEI Orientation?

Same per- k loop as §4.2, but the regression interacts `treat` with the respondent’s z-scored DEI index (`dei_index_z`, the canonical Individual DEI Index from §2). The treatment effect at each k is then evaluated at low (-1 SD), mid (0), and high ($+1$ SD) of the DEI index distribution via the linear combination $\hat{\beta}_{\text{blind}} + q\hat{\beta}_{\text{blind} \times \text{DEI}}$, with 95% CIs from $\sqrt{v'\Sigma v}$ where $v = (1, q)$. The substantive question: do pro-DEI respondents pick more productive candidates under blinding than anti-DEI respondents do?

TE on hired candidates' actual coding score, by respondent's DEI index level

Rows: TE evaluated at -1, 0, +1 SD of the within-role z-scored DEI index. Columns: HR vs Engineer. Bands: 95% CI from the linear combination of treat::blind and treat::blind:dei_index_z.

Table 6: Per- k blinding TE on actual coding score, by respondent DEI index level (cells: estimate (clustered SE); stars: $*p<0.10$, $**p<0.05$, $***p<0.01$).

6.4 Does Blinding's Productivity Effect Differ by Firm DEI-Targeting Policy?

Same per- k design as §4.3, but the moderator is now `firm_targets_fh` — a binary indicator for whether the respondent's firm formally targets Female or Hispanic candidates in hiring (constructed from `s5_policy_diversity`). Two-row $\times$ two-column grid: rows are **firm does NOT target** vs **firm DOES target**, columns are HR vs Engineer. The substantive question: does formal firm policy crowd out blinding's effect on the productivity of the selected pool?

Table 8: Per- k blinding TE on actual coding score, by firm DEI-targeting policy (cells: estimate (clustered SE); stars: $*p<0.10$, $**p<0.05$, $***p<0.01$).

k	HR Stage		Engineer Stage	
	Does NOT target	DOES target	Does NOT target	DOES target

6.4.1 Component Decomposition (test_case, readability, time_efficiency, space_efficiency)

Per-component decomposition by firm DEI-targeting policy (component standardized per k relative to nonblind). Columns: Stage x firm-targeting policy.

Visibility: engineers see test_case directly; HR sees none. Readability / time / space / runtime are unobserved.

Table 9: Per- k blinding TE on each coding component, by firm DEI-targeting policy. Cells: estimate (clustered SE).

k	Firm policy	Test Cases		Readability		Time Eff.		Space Eff.		Runtime	
		HR	Eng	HR	Eng	HR	Eng	HR	Eng	HR	Eng

6.5 Does Blinding's Productivity Effect Differ by Inter-Departmental DEI Misalignment?

Same per- k design, but the moderator is now `misalign_z`, the signed directional misalignment index from §3 (Eng: HR-overreach direction = rebellion conditions; HR: Eng-undercare direction = compensation conditions). Three-row $\times$ two-column grid: rows evaluate at low (-1 SD), mid (0), and high ($+1$ SD) of the index. The substantive question: does perceived inter-departmental DEI misalignment moderate the productivity-of-hired effect?

TE on hired candidates' actual coding score, by signed directional misalignment index

Rows: TE evaluated at -1, 0, +1 SD of the within-role z-scored signed directional misalignment index from §3. Columns: HR vs Engineer. Bands: 95% CI.

Table 10: Per- k blinding TE on actual coding score, by signed directional misalignment index (cells: estimate (clustered SE); stars: $*p<0.10$, $**p<0.05$, $***p<0.01$).

k	HR Stage			Engineer Stage

6.5.1 Component Decomposition (test_case, readability, time_efficiency, space_efficiency)

Per-component decomposition by signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x Misalign level.

Visibility: engineers see test_case directly; HR sees none. Readability / time / space / runtime are unobserved.

Table 11: Per- k blinding TE on each coding component, by signed directional misalignment index. Cells: estimate (clustered SE).

k	Misalign level	Test Cases		Readability		Time Eff.		Space Eff.		Runtime	
		HR	Eng	HR	Eng	HR	Eng	HR	Eng	HR	Eng

6.6 Does Blinding's Productivity Effect Vary Jointly by DEI Orientation and Inter-Departmental Misalignment?

Triple interaction extending §4.3 and §4.5: $\text{treat} \times \text{dei_index_z} \times \text{misalign_z}$, where misalign_z is the signed directional misalignment index from §3 (Eng: HR-overreach direction; HR: Eng-undercare direction). At each k the blinding TE is evaluated on a 3×3 grid of (DEI, Misalign) at $\{-1, 0, +1\}$ SD via the linear combination $\hat{\beta}_{\text{blind}} + d\hat{\beta}_{\text{blind} \times \text{DEI}} + m\hat{\beta}_{\text{blind} \times \text{Misalign}} + dm\hat{\beta}_{\text{blind} \times \text{DEI} \times \text{Misalign}}$, with 95% CIs from $\sqrt{v'\Sigma v}$ where $v = (1, d, m, dm)$ on the four blind-interaction coefs. Layout: 3×2 facet grid (rows: Misalign at $-1/0/+1$ SD; columns: HR vs Engineer), with within-panel color = DEI level. The substantive question: does pro-DEI orientation amplify or dampen blinding's productivity effect once we condition on the respondent's perceived inter-departmental DEI misalignment?

TE on hired candidates' actual coding score, by DEI index x signed directional misalignment

Rows: misalignment index at -1/0/+1 SD. Columns: HR vs Engineer. Within panel: respondent DEI index at -1/0/+1 SD. Bands: 95% CI from v' Sigma v with v selecting (treat::blind, treat::blin

Table 12: Per- k blinding TE on actual coding score, triple interaction ($\text{DEI} \times \text{Misalign} \times \text{Role}$). Cells: estimate (clustered SE). Inner column labels L/M/H = Low/Mid/High DEI ($-1, 0, +1$ SD); top headers group by Role; middle headers by Misalign level ($-1/0/+1$ SD). Stars: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

6.6.1 Component Decomposition (test_case, readability, time_efficiency, space_efficiency)

Triple interaction ($\text{treat} \times \text{dei_index_z} \times \text{misalign_z}$) re-estimated separately for each lab subscore. Each component is plotted on its own page (3-by-2 facet: rows = misalign at $-1/0/+1$ SD, cols = role; within-panel color = DEI level), matching the §4.6 layout exactly.

Triple interaction --- TE on Test Cases by DEI x signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x DEI level; Rows: Misalign level.

Y-cap ± 0.6 SD.

Triple interaction --- TE on Readability by DEI x signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x DEI level; Rows: Misalign level.

Y-cap ± 0.6 SD.

Triple interaction --- TE on Time Efficiency by DEI x signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x DEI level; Rows: Misalign level.

Y-cap ± 0.6 SD.

Triple interaction --- TE on Space Efficiency by DEI x signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x DEI level; Rows: Misalign level.

Y-cap ± 0.6 SD.

Triple interaction --- TE on Runtime by DEI x signed directional misalignment (component standardized per k relative to nonblind). Columns: Stage x DEI level; Rows: Misalign level.

6.7 Alternative A.1 (HR only): Candidate-Level Selection Probability Model with `sc_advance`

The per- k loop in §4.2–§4.6 suffers from extreme discrete-sampling variance at the boundaries (at $k=1$ a single tie-break injects pure noise into the dependent variable; at $k=18$ the pools collapse to identical sets). For HR, we have a natural binary — `sc_advance`, the actual decision to advance a candidate to the engineering stage — which lets us re-estimate the same selection question on the full candidate-evaluator panel without any k threshold:

$$\underbrace{\text{sc_advance}_{ij}}_{\text{HR's advance decision}} \sim \text{TrueCoding}_i \times \mathbb{1}[\text{Blind}]_j \times \text{Moderator}_j \mid \text{Respondent FE, cluster on Respondent.}$$

Why HR only here: `sc_advance` is HR's natural single-decision move forward'' binary; engineers do not produce a comparable single-shot binary on the firm side --- they instead deliver an `\emph{ordering}` over the 18 resumes, from which any binary is necessarily a top- k thresholding (which is exactly the §4.2 design we are trying to escape). For the engineer side we therefore push the analogousdoes blinding strengthen the link between true ability and selection'' question into a k -loop variant in §4.8 below.

With respondent FE, all between-respondent terms (`treat::blind`, the moderator main effect, and their two-way interaction) are absorbed; identification of the within-respondent slopes and their cross-products comes from variation in true coding ability across the 18 resumes a respondent rates. The substantive coefficients of interest are:

- **True Coding $\times$ Blind** — the central efficiency claim. > 0 means blinding tightens the link between objective ability and being advanced.
- **True Coding $\times$ Blind $\times$ M** — whether blinding's tightening of that link itself depends on the moderator (DEI orientation, firm DEI policy, or inter-departmental DEI misalignment).

Table 13: Alternative A.1 — HR Candidate-Level Selection Probability Model (LHS: `sc_advance`). LPM with respondent FE and display-order (`r_do`) FE; two-way clustered SEs on (respondent, resume) in parentheses. Col (1): pooled (no moderator). Cols (2)–(4): triple interactions with respondent DEI Index (z), firm DEI-targeting policy (binary, Female/Hispanic), and signed directional misalignment (z). Resume-content FE intentionally not absorbed (would kill the True Coding main-effect row); Respondent Characteristics and Q-version FE absorbed by Respondent FE so not separately included.

6.8 Alternative A.2 (k -loop): Selection Probability for Both Roles, Looping over k

Relationship to §4.2–§4.6: Because engineers do not give a single advance/no-advance decision, the analog of §4.7 for engineers requires picking a binary — and the only natural ones are the k -thresholded indicators `hr_passk` / `eng_topk`. Doing so produces what is essentially the LHS↔RHS *dual* of §4.2: where §4.2 conditions on the selected pool and asks *\emph{Is the average true coding score of the selected k higher under blinding?}*, ' §4.8 instead uses the full candidate-evaluator panel and asks *Is true coding ability a stronger predictor of being one of the selected k under blinding?*' Mathematically the two are not identical (different estimands and different units), but they are tightly linked: if blinding raises the average true score of the chosen k , it must be (approximately) because blinding has steepened the within-respondent gradient of selection probability on true ability. The advantage of the dual specification is that the panel sample size at every k is the full $N \approx 5,238$ candidate-evaluator observations, which compresses the standard errors that explode in §4.2 at low k .

$$\underbrace{\text{Selected}_{ij}^{(k)}}_{\substack{\text{HR: hr_pass}_k \\ \text{Eng: eng_top}_k}} \sim \text{TrueCoding}_i \times \mathbb{1}[\text{Blind}]_j \mid \text{Respondent FE, cluster on Respondent}, \quad k = 1, \dots, 18.$$

The plotted quantity is the per- k `true_coding_z × treat::blind` coefficient: the change in the within-respondent linear-probability slope of selection on true coding ability when going from non-blind to blind review. Positive means blinding tightens the ability-selection link. Bands are 95% CIs from clustered SEs on respondent.

Slope shift in P(selected at top-k) per 1 SD true coding ability (blind – nonblind)

Per-k change in the within-respondent LPM slope of selection on true coding ability under blinding (treat::blind x true_coding_z coefficient)

LPM with respondent FE + display-order (r_do) FE; two-way clustered SE on (respondent, resume). Resume-content FE intentionally not absorbed (would kill the true_coding_z slope). Po:

Table 14: Per- k $\text{true_coding_z} \times \text{treat}::\text{blind}$ coefficient (HR vs Engineer). LPM with respondent + r_do FE; resume-content FE intentionally omitted (would absorb true_coding_z). Cells: estimate (two-way clustered SE on respondent, resume). Stars: $*p<0.10$, $**p<0.05$, $***p<0.01$.

6.9 Alternative B: Evaluator-Level Rank Correlation (“Accuracy Score”)

Both prior alternatives still operate on the resume-evaluator long panel. Alternative B collapses that panel to one number per evaluator and asks a different but complementary question: across the 18 resumes a single evaluator rated, *how well does their overall ranking of those 18 resumes line up with the objective ranking by lab coding score?* For each respondent r we compute

$$\rho_r = \text{cor}\left(\text{rank}(\widehat{\text{sc_overall}}_{r,\cdot}), \text{rank}(\text{overall_score}_{\cdot})\right) \in [-1, +1],$$

the Spearman rank correlation between the evaluator’s overall ratings (`sc_overall_z`) and the resumes’ objective lab coding scores (`overall_score`). $\rho_r = +1$ means the evaluator’s ranking is identical to the objective ranking; $\rho_r = 0$ means pure noise; $\rho_r = -1$ means perfectly inverted. Spearman is rank-based, so the choice between raw and standardized versions of either input is irrelevant. We then regress the Fisher-z transform $\tilde{\rho}_r = \tanh^{-1}(\rho_r)$ (variance-stabilized, unbounded) on treatment and a moderator:

$$\tilde{\rho}_r \sim \mathbb{1}[\text{Blind}]_r \times \text{Moderator}_r + \text{controls}, \quad \text{HC1 robust SEs.}$$

Each observation is one evaluator (one row), so no clustering is needed — independence is by design. **Blind** positive $\Rightarrow$ blinding raises rank-alignment with truth on average; **Blind** $\times$ M nonzero $\Rightarrow$ that improvement varies with the moderator.

Distribution of evaluator-level Accuracy Score (Spearman rho between `sc_overall_z` and `overall_score` across 18 resumes)

Dashed lines: arm-specific means. $\rho > 0$ = evaluator’s overall ranking aligns with objective coding ability; $\rho < 0$ = anti-aligned.

Table 15: Alternative B — Evaluator-Level Accuracy Score: Fisher-z transformed Spearman rank correlation between the evaluator’s overall ratings and resumes’ objective lab coding scores across the 18 resumes they rated. OLS with HC1 robust SEs in parentheses; one observation per evaluator (no clustering). Resume-content / Display Position / Respondent FEs not applicable (respondent-level regression). Standard demographic Respondent Characteristics (resp_gender, resp_race, s2_educ, s2_income) absorbed in both HR and Eng specs. Eng additionally absorbs coding-language FEs (resp_python, resp_java), which are Eng-only survey items.
